Abstract

In this note we wish to complement some recent work in the cosmological literature concerning the Weyl conformal curvature tensor and its parts. In particular, we shall give a clear–cut definition of the Newtonian limits of electric and magnetic parts of the Weyl tensor. We also discuss that only a subset of the relativistic equations is needed to obtain a closed system of equations in the Newtonian limit.

PACS: 98.80.Hw, 04.20.Cv

1 Introduction

In a recent paper Bertschinger & Jain (1994) [3] attempted to derive a closed Newtonian system for the evolution of fluid quantities (density, expansion, shear, etc.) by looking at the Newtonian limit of the corresponding equations in general relativity. The idea was to obtain “local” evolution equations in terms of a coupled system of ordinary differential equations (while only the initial data are constructed non–locally) in order to simplify the solution of the problem of gravitational motion and to answer the question whether the gravitational collapse in general ends in sheet–like (oblate), or filamentary (prolate) objects.

Thereafter, a considerable amount of work has been spent on supporting or disproving this goal (Matarrese *et al.* 1994 [26], Bertschinger & Hamilton 1994 [2], Kofman & Pogosyan 1995 [21], Bruni *et al.* 1995 [6], Lesame *et al.* 1996 [25], Ellis & Dunsby 1997 [18], Matarrese 1996 [27], Matarrese & Terranova 1996 [28]), and others. Some of these papers are even concerned with new post–Newtonian theories (Bertschinger & Hamilton 1994 [2], see the discussion of that paper by Ellis & Dunsby 1997 [18]).

We here wish to complement these works by focusing on two aspects of the problem: firstly, we present a clear–cut derivation of the Newtonian limit of fluid evolution equations in a 4–dimensional “frame theory” developed by one of us (Ehlers 1981, 1991 [13, 14]). This theory covers both Einstein’s and Newton’s theory of gravitationally interacting matter and allows to properly *define* the Newtonian limit. We shall re–address questions related to the magnetic part of the Weyl tensor.

Secondly, we discuss that only a subset of the general relativistic equations is needed to obtain a closed Newtonian system, and we shall establish the relation to the Newtonian Lagrangian framework formulated first by Buchert & Götz (1987) [7], in Newtonian cosmology by Buchert (1989) [8], and reviewed by Buchert (1996) [9] and Ehlers & Buchert (1997).

(Throughout this paper greek indices run through $0 \dots 3$, and latin indices through $1 \dots 3$, the signature of the metric is $(-, +, +, +)$.)

2 The Newtonian limit of the Weyl tensor and its parts

In the recent cosmological literature there have been discussions on the role of the Weyl conformal curvature tensor, particularly its “magnetic” part, in the Newtonian limit of general relativity. These considerations suffer from the fact that claims are made about that limit without any reference to, or use of, a *definition* of that limit. However, a clear-cut (and useful!) definition has been given long ago (Künzle 1976 [23], Künzle & Nester 1984 [24], Ehlers 1981, 1991 [13, 14], Brauer *et al.* 1994 [5]).

Here we shall employ a “frame-theory” which covers, in a common 4-dimensional spacetime formalism, Newton’s as well as Einstein’s theory. In it, a parameter $\lambda = c^{-2}$ serves to distinguish between the two theories, and the limit is taken as $\lambda \rightarrow 0$. In that formalism one uses a temporal metric $t_{\alpha\beta}$ and (inverse) spatial metric $s^{\alpha\beta}$, related by:

$$t_{\alpha\beta}s^{\beta\gamma} = -\lambda\delta_{\alpha}^{\gamma}. \quad (1)$$

In the GR-case, $\lambda > 0$ and $g^{\alpha\beta} = s^{\alpha\beta}$, $g_{\alpha\beta} = -\lambda^{-1}t_{\alpha\beta}$, whereas in Newton’s theory, $\lambda = 0$ and $t_{\alpha\beta} = t_{,\alpha}t_{,\beta}$, with t the absolute time. In the limit $\lambda \rightarrow 0$, the Lorentz metrics $g_{\alpha\beta}$, $- \lambda g_{\alpha\beta}$ degenerate, corresponding to the fact that the light cones “open up” and convert into the Newtonian hyperplanes of constant absolute time (for details see: Ehlers 1981, 1991 [13, 14]).

In the notation of the frame-theory, the definition of the Weyl tensor for $\lambda > 0$ reads:

$$C^{\alpha}{}_{\beta\gamma\delta} = R^{\alpha}{}_{\beta\gamma\delta} - \delta_{[\gamma}^{\alpha}R_{\delta]\beta} - \lambda^{-1} \left\{ t_{\beta[\gamma}R_{\delta]\varepsilon}s^{\varepsilon\alpha} + \frac{1}{3}\delta_{[\gamma}^{\alpha}t_{\delta]\beta}R_{\lambda\mu}s^{\lambda\mu} \right\}. \quad (2)$$

This expression is meaningless for $\lambda = 0$. However, if we use the field equation

$$R_{\alpha\beta} = 8\pi G \left(t_{\alpha\gamma}t_{\beta\delta} - \frac{1}{2}t_{\alpha\beta}t_{\gamma\delta} \right) T^{\gamma\delta} - \Lambda t_{\alpha\beta} \quad (3)$$

of the frame-theory, valid for $\lambda \geq 0$, to eliminate $R_{\alpha\beta}$ from equation (2), we get:

$$C^{\alpha}{}_{\beta\gamma\delta} = R^{\alpha}{}_{\beta\gamma\delta} - 8\pi G \left\{ \delta_{[\gamma}^{\alpha}t_{\delta]\lambda}t_{\beta\mu}T^{\lambda\mu} - t_{\beta[\gamma}t_{\delta]\varepsilon}T^{\varepsilon\alpha} - \frac{2}{3}\delta_{[\gamma}^{\alpha}t_{\delta]\beta}t_{\lambda\mu}T^{\lambda\mu} \right\}. \quad (4)$$

This formula is meaningful even for $\lambda = 0$ (the λ^{-1} -terms in (2) cancel because of the λ in (1)). We therefore *define* the Weyl tensor in the frame-theory by Equation (4). This definition is appropriate; for if a sequence of GR-solutions has a Newtonian solution as a limit, then the limit of $C^{\alpha}{}_{\beta\gamma\delta}$ is indeed given by Equation (4).

In the Newtonian case, $\lambda = 0$, (4) simplifies, because of $t_{\alpha\beta} = t_{,\alpha}t_{,\beta}$, to

$$C^{\alpha}{}_{\beta\gamma\delta} = R^{\alpha}{}_{\beta\gamma\delta} - \frac{8\pi G}{3}\rho t_{,\beta}\delta_{[\gamma}^{\alpha}t_{,\delta]}. \quad (5)$$

The “electric” and “magnetic” parts of $C^{\alpha}{}_{\beta\gamma\delta}$ with respect to any 4-velocity u^{α} follow from (5); they read:

$$E^{\alpha}{}_{\gamma} = R^{\alpha}{}_{\beta\gamma\delta}u^{\beta}u^{\delta} - \frac{4\pi G}{3}\rho(\delta_{\gamma}^{\alpha} - u^{\alpha}t_{,\gamma}); \quad (6)$$

$$H_{\alpha\gamma} = \frac{1}{2}\eta_{\alpha\beta\lambda\mu}s^{\mu\nu}C^{\lambda}{}_{\nu\gamma\delta}u^{\beta}u^{\delta} = 0. \quad (7)$$

The vanishing of $H_{\alpha\beta}$ in the Newtonian limit can be understood more physically as follows: In GR, $H_{\alpha\beta}$ measures the relative rotation of nearby, freely falling gyroscopes due to gravitomagnetism (Sachs 1960 [29], Appendix¹). This effect is absent in Newton’s theory in which the parallelism of spatial vectors is

¹the relevant formula contains a misprint: the correct version is $H^a{}_{[g]} = \frac{1}{2}\eta^{a\ell m}R_{\ell m j k}u_i\delta x^j u^k$.

path independent, in other words, parallel gyroscopes remain parallel if subject to nothing but inertia and gravity.

Investigation of the general case of exact solutions of general relativity with $H_{\alpha\beta} = 0$ and $\omega_{\alpha\beta} = 0$ has been attempted by Barnes & Rowlingson (1989) [1]. However, they have not investigated the propagation of the dynamical constraint $H_{ab} = 0$, which is needed for statements about classes of exact solutions². Further investigations of such classes of motion termed “silent universes” may be found in Croudace *et al.* 1994 [11], Bruni *et al.* 1995 [6], Matarrese 1996 [27] (and ref. therein), and van Elst & Ugla 1997 [20].

3 Discussion of the equations in the Newtonian limit

In 3-dimensional notation, (6) yields, as expected, the Newtonian tidal tensor defined as the trace-free part of the gravitational field tensor ($g_{i,j}$) (a comma denotes derivative with respect to Eulerian coordinates):

$$E_{ij} := g_{i,j} - \frac{1}{3} \delta_{ij} g_{\ell,\ell} , \quad (8)$$

with

$$E_{[ji]} = 0 ; \quad E_{ii} = 0 . \quad (9)$$

Like any Eulerian field, the Newtonian tidal tensor of the gravitational field strength $\vec{g}$ can be written explicitly in terms of Lagrangian coordinates as follows:

$$E_{ij} = g_{i|k} J_{kj}^{-1} - \frac{1}{3} \delta_{ij} g_{\ell|k} J_{k\ell}^{-1} , \quad (10)$$

where a vertical slash denotes derivative with respect to Lagrangian coordinates.

Introducing the diffeomorphic mapping $\vec{f}_t : \vec{x} = \vec{f}(\vec{X}, t)$, which sends fluid elements from their (initial) Lagrangian position $\vec{X}$ to a point $\vec{x}$ in Eulerian space at time t , and using the expression for the Jacobian of the inverse mapping $\vec{h} = \vec{f}^{-1}$,

$$\vec{g}[\vec{x}, t] := \ddot{\vec{f}}(\vec{h}[\vec{x}, t], t) , \quad J := \det(f_{i|k}) , \quad (11)$$

$$h_{j|l} = \frac{1}{2J} \epsilon_{lpq} \epsilon_{jrs} f_{p|r} f_{q|s} , \quad (12)$$

we can write the tidal tensor explicitly in terms of $\vec{f}$:

$$E_{ij} = \frac{1}{2J} \left(\epsilon_{jpq} \mathcal{J}(\ddot{f}_i, f_p, f_q) - \frac{1}{3} \epsilon_{opq} \mathcal{J}(\ddot{f}_o, f_p, f_q) \delta_{ij} \right) . \quad (13)$$

Thus, any trajectory field $\vec{f}$ which obeys the Lagrange–Newton system (Buchert & Götz 1987 [7] ($\Lambda = 0$) and Buchert 1989 [8] ($\Lambda \neq 0$); Ehlers & Buchert 1997 [16]),

$$\mathcal{J}(\ddot{f}_j, f_j, f_k) = 0 , \quad (14)$$

$$\mathcal{J}(\ddot{f}_1, f_2, f_3) + \mathcal{J}(\ddot{f}_2, f_3, f_1) + \mathcal{J}(\ddot{f}_3, f_1, f_2) - \Lambda J = -4\pi G \overset{0}{\rho} , \quad (15)$$

determines the evolution of the tidal tensor via (10).

In (14) and (15), $\mathcal{J}(\mathcal{A}, \mathcal{B}, \mathcal{C})$ denotes the functional determinant of any three functions $\mathcal{A}(\vec{X}, t)$, $\mathcal{B}(\vec{X}, t)$ and $\mathcal{C}(\vec{X}, t)$ with respect to Lagrangian coordinates $\vec{X}$, $\overset{0}{\rho}$ is the initial density field and Λ the cosmological constant.

²This issue was considered later with the additional assumption $p = 0 \Rightarrow \dot{u}^a = 0$ in van Elst *et al.* 1997 [19], where for the general case without any symmetries and Weyl tensor of Petrov type I no complete results could be obtained.

We may use Equation (13) to state the Lagrange–Newton system (14) and (15) in a different way: it is equivalent to the condition that E_{ij} is symmetric and tracefree (Buchert 1996 [9]): We insert (15) into (13) and write

$$E_{ij} = \frac{1}{2J} \epsilon_{j p q} \mathcal{J}(\ddot{f}_i, f_p, f_q) - \frac{1}{3} \left(\Lambda - \frac{4\pi G}{J} \rho \right) \delta_{ij} . \quad (16)$$

Then,

$$E_{[ij]} = 0 \Leftrightarrow (14) ; \quad (17)$$

$$E_{ii} = 0 \Leftrightarrow (15) . \quad (18)$$

This demonstrates that no equation involving H_{ij} is needed in the Newtonian limit to close the system. Indeed, for $H_{\alpha\beta} = 0$, the relativistic system of equations for the fluid variables expansion (θ), vorticity ($\omega_{\alpha\beta}$), shear ($\sigma_{\alpha\beta}$), “electric” ($E_{\alpha\beta}$) and “magnetic” ($H_{\alpha\beta}$) parts of the Weyl tensor — derived by one of us (Ehlers 1961; translated 1993 [12]) and Trümper 1965 [31], and reviewed by Ellis 1971 [17] — reduces to the system

$$\dot{\rho} = -\theta\rho , \quad (19)$$

$$\dot{\theta} = \Lambda - \frac{1}{3}\theta^2 + 2(\omega^2 - \sigma^2) - 4\pi G\rho , \quad (20)$$

$$\dot{\omega}^\alpha = -\frac{2}{3}\theta\omega^\alpha + \sigma^\alpha{}_\beta\omega^\beta , \quad (21)$$

$$\dot{\sigma}_{\alpha\beta} = -\sigma_{\alpha\gamma}\sigma^\gamma{}_\beta - \omega_\alpha\omega_\beta + \frac{1}{3}h_{\alpha\beta}(2\sigma^2 - \omega^2) - \frac{2}{3}\theta\sigma_{\alpha\beta} - E_{\alpha\beta} , \quad (22)$$

$$\dot{E}_{\alpha\beta} = -h_{\alpha\beta}\sigma^{\gamma\delta}E_{\gamma\delta} - \theta E_{\alpha\beta} + E_{\gamma(\alpha}\omega_{\beta)}{}^\gamma + 3E_{\gamma(\alpha}\sigma_{\beta)}{}^\gamma - 4\pi G\rho\sigma_{\alpha\beta} , \quad (23)$$

where $h^{\alpha\beta} = g^{\alpha\beta} + u^\alpha u^\beta$ is the spatial projection tensor. Recall that a solution of this closed set of equations delivers at best an approximation that needs to be controlled. Resulting solutions will have to be subjected to the propagation constraint $\dot{H}_{\alpha\beta} = 0$ to find the exact solution classes. This constraint will likely leave only highly symmetric solutions like the Lemaître–Tolman–Bondi and the Szekeres models, since, in general, a non-vanishing magnetic part of the Weyl tensor is generated by evolving a system with initially vanishing magnetic part.

In the Newtonian limit $\lambda \rightarrow 0$ the spatial parts of the equations (19)–(22) are equivalent to those derived from Newtonian theory (compare Szekeres & Rankin 1977 [30] and the discussions by Kofman & Pogosyan 1995 [21], Lesame *et al.* 1996 [25], Buchert 1996 [9] and Matarrese 1996 [27]). The Lagrange–Newton–System (14) and (15) can be already obtained from (19)–(21) together with the decomposition $\sigma_{ij} + \omega_{ij} + \frac{1}{3}\theta\delta_{ij} = v_{i,j}$.

Note added 2009: Some examples of Newtonian limits of relativistic spacetimes have been published by Ehlers 1997 together with more details on the Newtonian limit in the frame–theory formalism used here [15]. Furthermore, it is possible to write the Einstein equations in terms of symmetry conditions imposed on the electric and magnetic parts of the Weyl tensor similar to writing the Lagrange–Newton system (14, 15), since both parts of the Weyl tensor contain all information. The investigation of this formulation together with the corresponding Newtonian limit will be published elsewhere. Related remarks on the Newtonian limit in the framework of Cartan’s formulation of Einstein’s equations may be found in Buchert (2008) [10], Sect. 4.2.1.

Acknowledgments

In 1996, TB was supported by the “Sonderforschungsbereich 375–95 für Astro–Teilchenphysik der Deutschen Forschungsgemeinschaft”. He would like to thank the Albert–Einstein–Institut in Potsdam for

generous hospitality during a working visit in 1996, where this work has been written. TB would also like to thank Henk van Elst for digging out the preprint, as well as for help and comments during the preparation of this manuscript.
